

Slide Scanner Assembly and Drawings

May 18, 2021

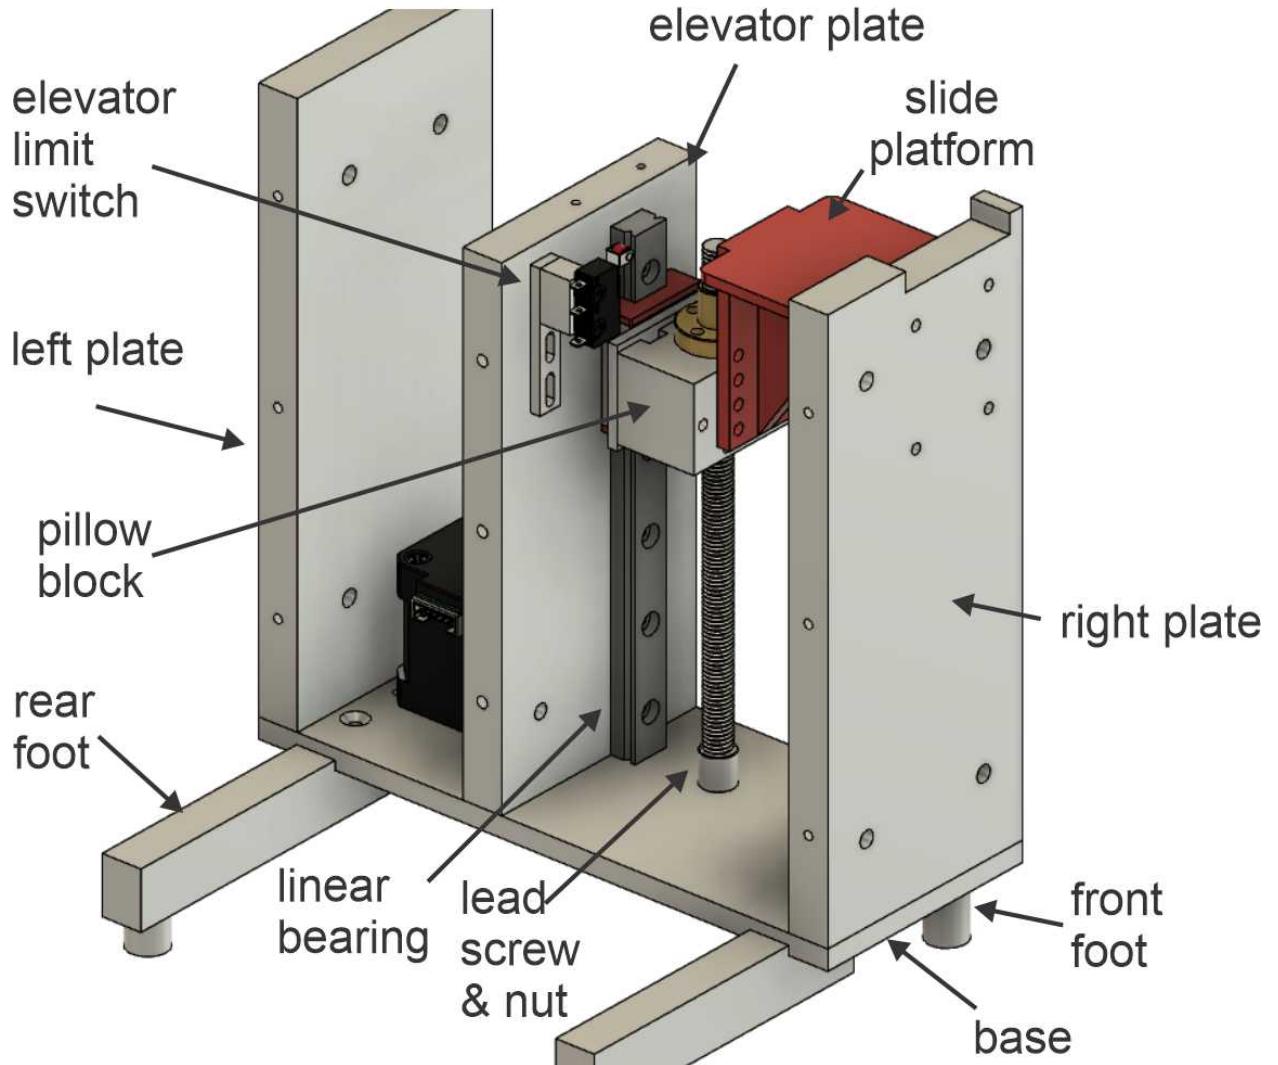

This section will outline the assembly of the slide scanner and a list of drawings of the individual parts. The best way to appreciate the assembly is with the Fusion 360 model which allows individual parts to be highlighted and show the arrangement of the parts in a 3D model. I have made working drawings of each part of which there are over 70 individual parts, some of which are in pairs. I have chosen to dimension these drawing in a way that suits my needs but may not be suitable for everyone. If a different dimension is needed, I would urge using the Fusion model to find any missing dimensions. Hopefully, these drawings should serve as a good first step. The main frame of the scanner was designed to be constructed with $\frac{1}{2}$ " Delrin. Delrin often comes slightly oversized. The system could be assembled with the raw Delrin without facing it to $\frac{1}{2}$ ". However, it will be necessary to take into account the placement of assembly holes. There are likely to be small errors in the model with regard to actual hole dimensions for screws, but the drawing indicates whether the holes are threaded (thrd) or clearance (clear) holes which can range from 0-80 to 8-32 threads.

A number of parts are best made as 3D printed parts. These parts are listed as 3D printed parts on the print. While some of these could be made with traditional milling, I choose to use 3D printing as much as possible. The prints will be arranged in four sections: "Frame", "Shuttle", "Height Sensor" and "Arduino Enclosure". Under each of these sections there are drawings which are referenced by the names as listed in the components from the Fusion 360 model. Each section will have a little overview which shows its parts and how they are assembled.

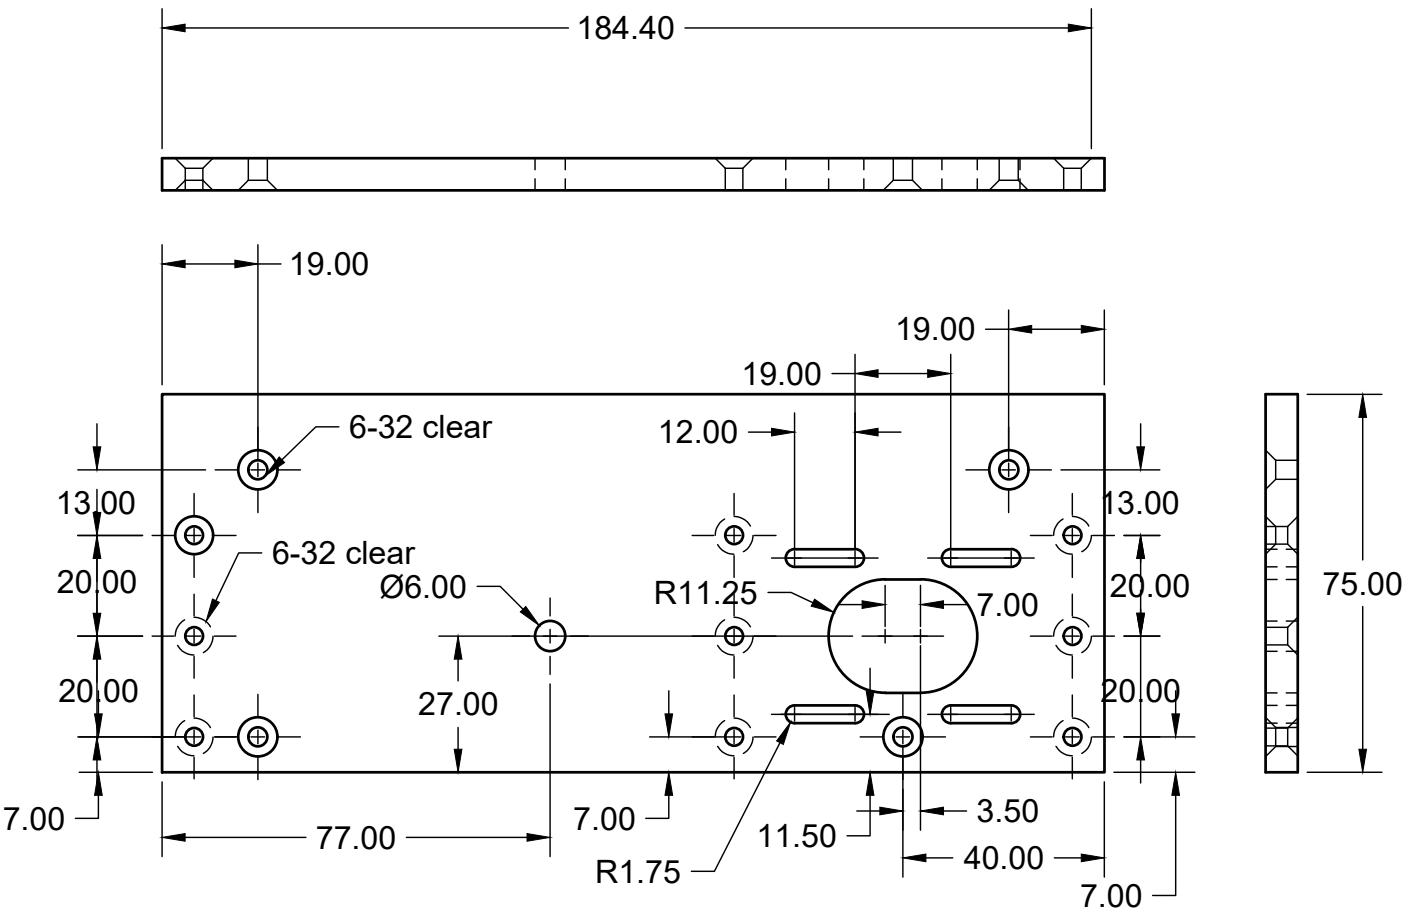

This document is distributed in the hope that it will be useful, but without any warranty and without even the implied warrant of merchantability or fitness for a particular purpose. Errors may be present in the drawings; however, the model will be largely consistent. It would be best to become familiar with the Fusion model and duly consider the effect of different stock used if different from the model.

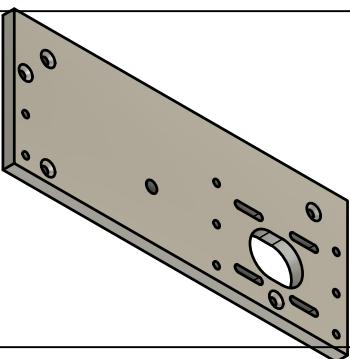

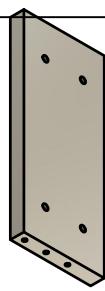

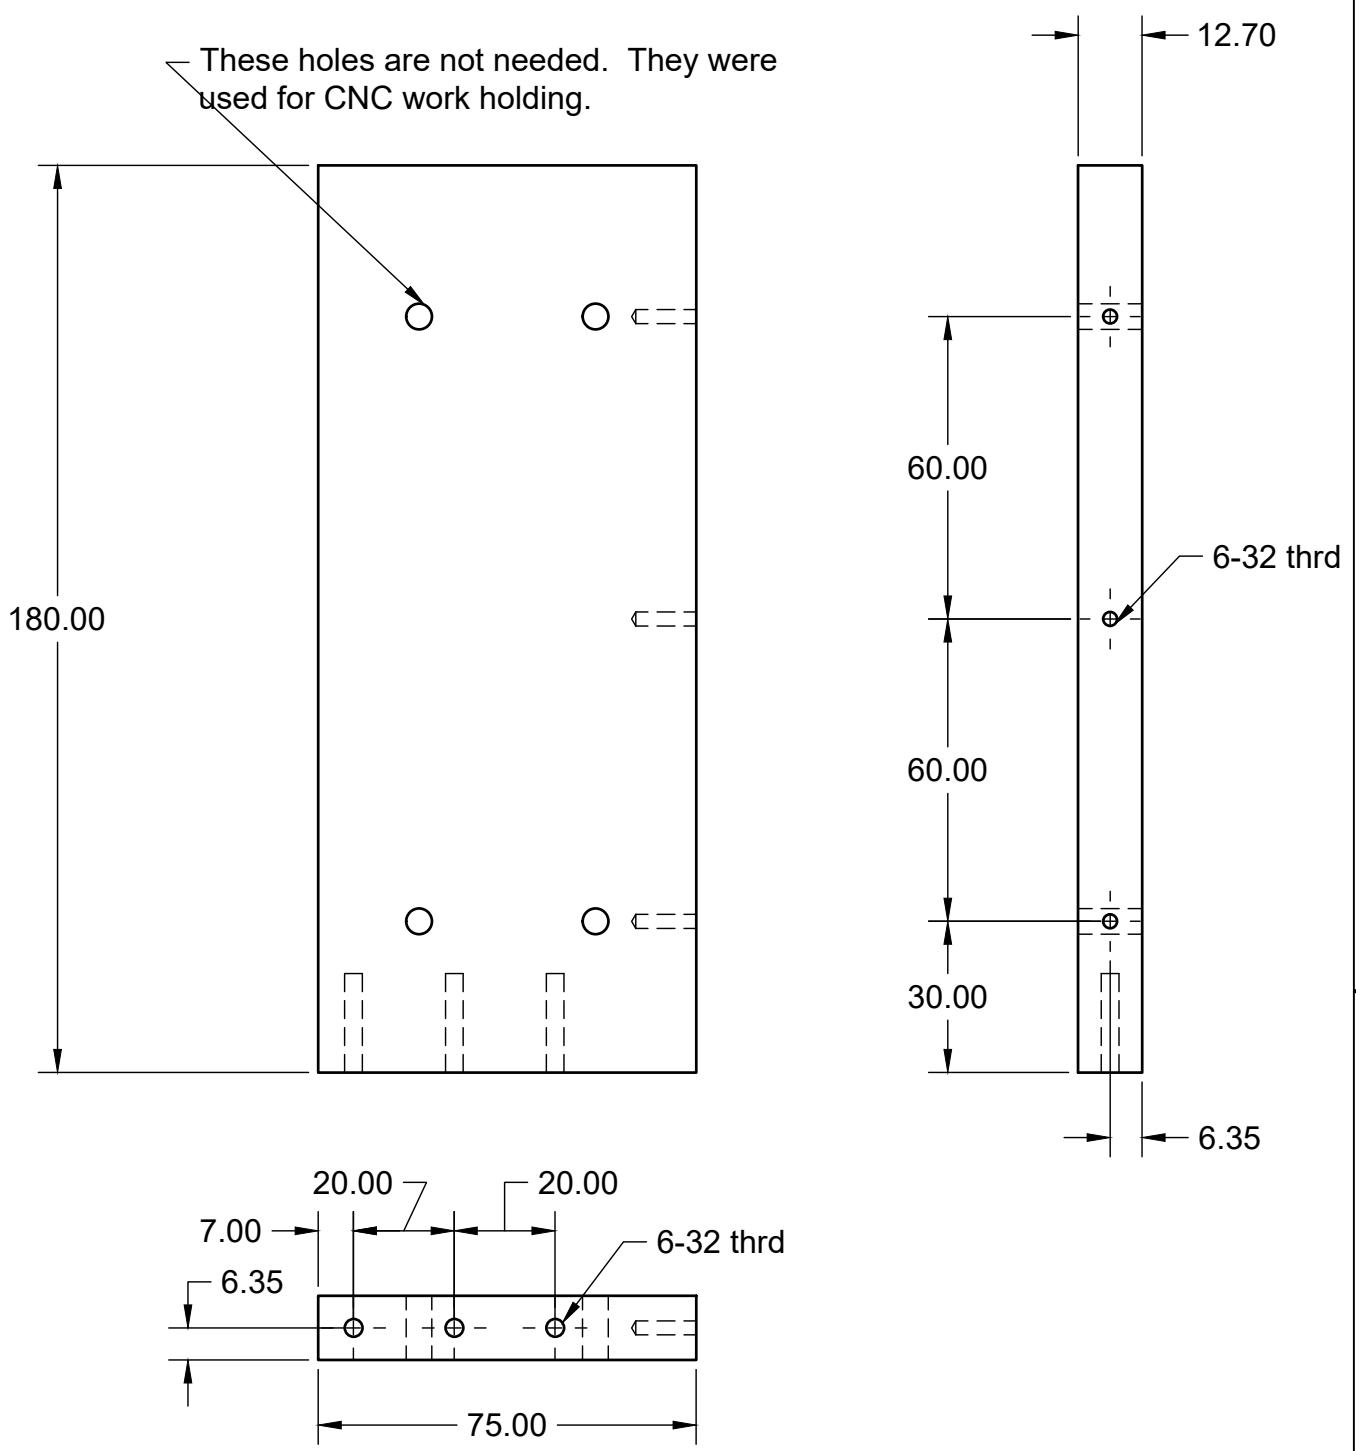

Frame Assembly

This assembly is composed of a four main plates: right, elevator, left and base. The whole assembly is supported on feet in the front and rear. The extension of the rear foot is to balance the mass distribution of the scanner. Within this assembly the linear bearing is attached to the elevator plate. The lead screw turns on the base and moves a pillow block attached to the linear bearing in a vertical direction. This supports the slide platform (red) which moves the slides to the top of the scanner. A limit switch attached to the elevator plate defines the upper limit of motion of the lead screw. The drawings that follow will detail each of these parts. Refer to the Fusion model to gain a better understanding of the layout of each component.

This part has two recesses in the surface in contact with the pillow block connector plate. This is to provide a vacancy for the heads of two M3 screws which hold the pillow block connector plate to the lead screw glide. An alternative design would be to use longer M3 screws to connect the pillow block to the linear bearing guide without the connector plate. This would simplify the design. In this case, the depth of the pillow block will need to be adjusted for the missing connector plate.

Height Sensor Assembly

This assembly detects when the slide reaches the correct location as it is lifted by the elevator. The limit switch is mounted on a rotating member which is held in place by a pair of magnets that serve to hold the limit switch "closed" as seen in this drawing. The orientation and height of the switch can be controlled by three different mechanisms. The most sensitive is controlled by the adjuster knob. The names are aligned with the names on the Fusion 360 model and the model should be referenced for more detail.

The height sensor has two positions: closed (a) and open (b). When scanning, the sensor is closed to detect each slide when it arrives at the proper height. When open (a), the hopper is exposed which permits loading of slides into the hopper. The magnets are seen in both views and shown green. The orientation of the magnets is such that they attract each other normally forcing the switch to the closed position. A gentle pull on the body of the limit switch will allow it to be pulled open. Rotating the knob defines the position of the switch in the closed position. Using this knob, the trigger position of the switch can be fine tuned during operation.

Camera Support

The camera is supported by rails on each side of the scanner frame. It is composed of 5 parts. The board which holds the camera is supported by a left and right set of rails. The right rail has an offset piece (red) which allows uninterrupted movement of the shuttle. The camera plate was made of $\frac{1}{2}$ " plywood which the channels were $\frac{3}{4}" \times \frac{3}{4}" \times \frac{1}{8}"$ aluminum channel. The rail offset was machined from a Delrin block.

Arduino Assembly

This is the encloser for the Arduino Uno and the LCDDisplay on the front of the scanner. It is composed of two parts: the box and the top panel. The box and top panel are assembled with screws as shown in (a). The enclosure and the front panel were 3D printed. The top panel supports the LCDDisplay board (a & b) with screws. A toggle switch is used to turn on the power. The LCDDisplay shield plugs into a screw connector breakout shield which in turn plugs into the Arduino Uno. The three board are suspended from the top panel. The underside of the top panel is shown in (c) with the bottom of the LCDDisplay board. To drive the buttons on the LCDDisplay board, small brass buttons (b & d) are machined which fit into holes for the front panel and align with LCDDisplay board.

This is a complex part and only a few representative dimensions are shown. This part is best made by 3D printing. The .stl file can be obtained from the Fusion 360 model.
